Application No. 00 945 280.6 - 1260	Ref. 71863.2p	Date 05.03.2004
Applicant Warren Rogers Associates, Inc.		

Communication under Rule 51(4) EPC

You are informed that the Examining Division intends to grant a European patent on the basis of the above application with the text and drawings as indicated below:

In the text for the Contracting States:
AT BE CH CY DE DK ES FI FR GB GR IE IT LI LU MC NL PT SE

Description, Pages

1-56 as published

Claims, Numbers

1-22 received on 28.11.2003 with letter of 26.11.2003

Drawings, Sheets

1/12-12/12 as published

With the following amendments to the above-mentioned documents by the examining division

Description, Pages 1,3,4,6-8

A copy of relevant documents is enclosed

The title of the invention in the three official languages of the European Patent Office, the international patent classification, the designated Contracting States, the registered name of the applicant and the bibliographic data are shown on the attached EPO Form 2056.

THIS PAGE BLANK (USPTO)

You are requested **within four months** of this notification

1. to file 1 set of translations of the claim(s) in the two other EPO official languages;

EUR

- 2a. to pay the fee for grant including the fee for printing up to and including 35 pages;
Reference 007

715.00

- 2b. to pay the printing fee for the 36th and each additional page;
number of pages: 37

Reference 008

370.00

3. to pay the additional claim fee(s) (Rule 51(7) EPC);
number of claims fees payable:

Reference 016

0.00

Total amount

1085.00

Concerning the possibility of a request for accelerated grant pursuant to Article 97(6) EPC, reference is made to OJ EPO 2001, 459.

If the grant, printing or claims fees are not paid, or the translations not filed, in due time the European patent application will be deemed to be withdrawn (Rule 51(8) EPC).

For all payments you are requested to use EPO Form 1010 or to refer to the relevant reference number.

If additional copies of the patent specification are required, you should request this in writing and quote Fee reference code 058 when making payment.

Translation of the priority document(s)

If the translation of the priority document(s), as required by Article 88(1) EPC, or the declaration according to Rule 38(5) EPC has not yet been filed, Form 2530 will be despatched separately. The translation is to be filed within the above mentioned time limit (Rule 38(5) EPC).

Note on payment of renewal fees

If a renewal fee falls due between notification of the present communication and the proposed date of publication of the mention of the grant of the European patent, publication will be effected only after the renewal fee and any additional fee have been paid (Rule 51(9) EPC).

Under Article 86(4) EPC, renewal fees are payable to the European Patent Office until the year in which the mention of the grant of the European patent is published.

Filing of translations in the Contracting States

Pursuant to Article 65(1) EPC the following Contracting States require a translation of the specification of the European patent in their/one of their official language(s) (Rule 51(10) EPC), **insofar** this specification will not be published in their/one of their official language(s)

- within **three** months of publication of the mention of such decision:

The date on which the European Patent Bulletin publishes the mention of the grant of the European patent will be indicated in the decision on the grant of the European patent (EPO Form 2006). In case of a valid extension the following Extension States require a translation of the **claims** in their official language within **three** months after publication of the mention of the grant of the European patent:

AL	ALBANIA
LT	LITHUANIA
LV	LATVIA

MK	MACEDONIA
RO	ROMANIA (requires translation of the specification)

The translation must be filed with the national Patent Offices of the Contracting or Extension States in accordance with the provisions applying thereto in the State concerned. Further details (e.g. appointment of a national representative or indication of an address for service within the country) are given in the EPO information brochure "National law relating to the EPC", and in the supplementary information published in the Official Journal of the EPO, or available on the EPO website.

Failure to supply such translation to the Contracting and Extension States in time and in accordance with the requirements may result in the patent being deemed to be void ab initio in the State concerned.

Note to users of the automatic debiting procedure

Unless the EPO receives prior instructions to the contrary, the fee(s) will be debited on the last day of the period of payment. For further details see the Arrangements for the automatic debiting procedure (see Supplement to OJ EPO 2, 2002).

Cross Reference to Related Applications

This is a continuation-in-part of serial no.
09/083,732, filed May 22, 1998, which is a continuation-in-
part of application serial no. 08/658,139, filed June 4,
1996, now U.S. Patent No. 5,757,664, and a continuation-in-
10 part of International patent application no. PCT/US97/09505,
with an international filing date of June 4, 1997.

Background of the Invention

The invention relates to monitoring the operational
performance of fluid storage systems. \longleftrightarrow

15

Large quantities of liquids and similar materials
are often stored in bulk storage containers or tanks, which
may be located above-ground, partially above-ground, or
completely below ground. Such containers or tanks are
generally connected by piping to flow-meters or dispensers.

20

For example, underground storage tanks (UST's) and,
occasionally, above-ground storage tanks (AST's) are used to
store petroleum products and fuel to be dispensed at
automobile service stations, trucking terminals, automobile
rental outlets, and similar operations through gasoline,
25 diesel, or kerosene dispensing pumps. Fuel product is
generally delivered to such facilities by a gravity drop
from a compartment in a wheeled transport means such as a
fuel delivery truck or an introduction of product through an
underground piping system. AST's or UST's are often located
30 at central distribution locations so that product can be
subsequently withdrawn from the tank system to be
transported for delivery to a variety of such facilities. A
distribution location with UST's or AST's may receive

deliveries of product from, e.g., a pipeline spur, wheeled transport, a barge, or a rail car.

Direct observation of the operating condition of such tanks and storage containers is difficult or impossible. The various methods for identifying the amount of product in tank systems have varying levels of accuracy, repeatability, and performance. Moreover, the accuracy of devices which measure the amount of product dispensed from the storage containers and tanks differs greatly, and may or may not be temperature compensated. The amount of product actually delivered to the tank system is often measured inaccurately and, frequently, not at all. Rather, the owner or operator of the tank or vessel usually records the invoiced amount of product delivered as the actual amount introduced to the tank system, without having any means of confirming whether the invoiced amount of product delivered is correct.

Consequently, effective management of such facilities is complicated by the numerous errors in the various measuring devices and procedures used to establish a baseline for management, planning and decisionmaking. Effective management requires the following:

1. Accurate measurement of the volume stored in the system.
2. Accurate determination of the volume dispensed from the system.
3. Accurate determination of the amount of product introduced into the system.
4. Identification of volumes added to or removed from the tank system which are not otherwise recorded.
5. Rapid identification of leakage from the tank system.

6. Continuous monitoring and diagnosis of the operating performance of all of the component measuring devices of the system.
7. Continuous analysis of sales data to predict demands of product from the system.
8. Determination of optimal reorder times and quantities as a function of ordering, transportation, holding, and penalty costs in order to minimize total costs of operation and/or to maximize profits.

Traditionally, these functions were performed crudely or, in many cases, not at all. Volume measurements were, and in many instances still are, based on imperfect knowledge of the geometry, dimensions, and configuration of the storage vessel. Also, dispensing meters are frequently miscalibrated. This is true even when tank systems are regulated, due to the breadth of tolerance permitted for individual sales as related to total tank volume. For example, deliveries from the delivery vehicle are almost always unmetered, additions of product from defueling vehicles are typically undocumented, and theft of the product is not uncommon.

Leakage of product has, in recent years, assumed a dimension far in excess of the mere loss of the product. Environmental damage can, and frequently does, expose the operator to very large liabilities from third party litigation in addition to U.S. Environmental Protection Agency (EPA)-mandated remediation which can cost in the range of hundreds of thousands of dollars. The EPA's requirements for leak detection are set forth in EPA Pub. No. 510-K-95-003, Straight Talk On Tanks: Leak Detection Methods For Petroleum Underground Storage Tanks and Piping (July 1991), ~~which is incorporated herein by reference/~~

<as defined in the appended claims>

To address these concerns, Statistical Inventory Reconciliation (SIR) was developed. The SIR method consists of a computer-based procedure which identifies all of the sources of error noted above by statistical analysis of the various and unique patterns that are introduced into the inventory data and, in particular, into the cumulative variances in the data when viewed as functions of product height, sales volumes, and time.

Summary of the Invention.

The present invention relates to an automatic SIR system that may continuously and automatically collect data from completely above-ground, partially above-ground, and completely below ground containers for statistical analysis. The invention addresses a variety of physical, business, operational and environmental issues associated with the bulk storage of liquids or pourable solids.

The present invention is an application of SIR that greatly enhances the ability to manage a facility effectively. It provides the means to characterize exactly the geometry, dimensions, and configuration of the storage vessel, identify overages and shortages in deliveries and unexplained additions and removals of product, and provide an accurate assessment of overall dispensing meter calibration. In addition, by accounting for such discrepancies, the present invention permits identification of leakage at rates less than .1 gallon per hour in all of its estimates to any prescribed tolerance. By increasing the number of measurements taken, the estimates can be derived at any desired level of tolerance.

The method of the present invention makes no assumptions as to the precision of any of the measuring devices used in various system configurations. Precision and calibration accuracies are derived from the data alone.

Also, it is not assumed that the tank system is leak free; the leak status of the system is determined from the data alone.

5 The method derives tank geometry, dimensions, and configuration, and their impact on the totality of cumulative inventory variances, as a function of product height in the tank. Correctness of dispensing meter calibration is verified in a similar manner by testing for randomness of cumulative variances as a function of varying sales volumes. Having confirmed that such remaining residual variances are random, reflecting only the inherent random noise of the measurement devices, the present method analyzes departures of the cumulative variance from the bounds determined by the calculated random noise level. All calculations as to the volumes added, removed, metered or leaking are based upon extended successive, simultaneous observations of meter and gauge readings. The number of observations incorporated in each such calculation is determined by computing confidence bands for the parameters of interest and extending data collection as necessary to achieve predetermined tolerances.

For example, the method of the present invention is capable of distinguishing between continuous losses consistent with leakage and one-time unexplained removals of the fluid product from the tank. The method may be used to ensure the accuracy of computed delivery volumes, which are determined and reported with confidence boundaries calculated for estimated delivered quantities.

30 The method can also be used to control and monitor the accuracy of purchase costs of fluids such as petroleum which are delivered to tanks. For example, motor fuel retailers may be charged by wholesalers for either net or gross volumes purported to have been delivered. A

determination that purchase charges are appropriate thus requires frequent simultaneous readings of sales, tank volumes and temperatures, which can be accomplished using the method of the present invention.

5 To accomplish these goals, the present invention involves estimating changes in product volume in a tank based on multiple data points and their respective likely errors measured continuously over a period of time. A software program is used to implement an algorithm that
10 employs concepts from matrix theory and mathematical statistics. The algorithm includes generating the product of a matrix and its transpose by successive additions of partial products of partitions of the matrix and their corresponding transposed matrix partitions to minimize the
15 storage requirements of the data collected. The compressed matrix data constitutes a complete and sufficient statistic for the parameters of interest. The algorithm thus permits the accumulation and storage of a large amount of data in a condensed form without sacrificing statistically useful
20 information, to obtain a statistically significant result with the required accuracy and reliability.

according to claim 1
In general, in one aspect, the invention features a method of monitoring a fluid storage and dispensing system including a dispensing apparatus. A quantity of fluid is
25 dispensed from the system using the dispensing apparatus based on an authorization. A plurality of measurement data is collected from the dispensing apparatus in a form readable by a computer. The plurality of measurement data is stored in a memory. The stored plurality of measurement
30 data are statistically analyzed to calculate a volume of fluid based on the plurality of measurement data collected from the dispensing apparatus.

~~WO 01/04586~~~~PCT/US00/16743~~

Implementations of the invention may also include one or more of the following features. The authorization may be based on information relating to a user requesting that the quantity of fluid be dispensed from the system.

5 The authorization may be provided by a fuel access control system.

The method may further include transmitting the plurality of measurement data to a processor to perform the statistically analyzing step. The plurality of measurement data may be stored in a compressed matrix format, which may be a product of a data matrix and a transpose of the data matrix. The dispensing apparatus may include a totalizer and a meter.

10

according to claim 8

In general, in another aspect, the invention

15 features a method of monitoring a fluid storage and dispensing system including a plurality of dispensing apparatus. A quantity of fluid is dispensed from the system using the plurality of dispensing apparatus based on an authorization. Measurement data is simultaneously collected

20 from the plurality of dispensing apparatus in a form readable by a computer. The collecting step is repeated to obtain a plurality of the measurement data, which are stored in a memory. The stored plurality of measurement data is statistically analyzed to calculate a volume of fluid based

25 on the plurality of measurement data collected from the plurality of dispensing apparatus.

Implementations of the invention may also include one or more of the following features. The authorization may be based on information relating to a user requesting

30 that the quantity of fluid be dispensed from the system. The authorization may be provided by a fuel access control system.

The method may further include transmitting the plurality of measurement data to a processor to perform the statistically analyzing step. The plurality of measurement data may be stored in a compressed matrix format, which may
5 be a product of a data matrix and a transpose of the data matrix.

according to claim 14,

In general, in another aspect, the invention features a fluid storage and dispensing system including a tank for storing fluid and a dispenser for dispensing fluid
10 from the tank. A fuel access control system enables the dispenser based on an authorization. Measurement apparatus collects measurement data corresponding to a quantity of fluid dispensed from the tank by the dispenser. A processor statistically analyzes the measurement data to calculate a
15 volume of fluid in the system.

Implementations of the invention may also include one or more of the following features. The system may further include a memory for storing the collected measurement data. The measurement apparatus may include a
20 totalizer and a meter.

The fuel access control system may be activated by a coded medium which contains identification information pertaining to the user and which constitutes a request to dispense fluid from the system. The authorization may be
25 based on information about a user requesting to dispense fluid from the system.

The processor may store the measurement data in a compressed data matrix format, which may be a product of a data matrix and a transpose of the data matrix.

30 An advantage of the present invention is that the accuracy and consistency of devices used to measure volume of product added to, removed from, and present in a fluid storage system may be determined.

~~WO 01/64586~~~~PCT/US00/18743~~

Another advantage of the present invention is that additions of material to the system, but not recorded as such, and volumes of product removed from the system which are not registered by measuring devices or otherwise recorded, may be identified.

Another advantage of the present invention is that discrete one-time unrecorded removals of product from the system may be distinguished from continuous losses consistent with leakage.

Another advantage of the present invention is that product leakage from all parts of the system, extending from the fill point to the point of discharge, may be identified and confirmed.

Another advantage of the present invention is that secular, seasonal trends and repetitive special demands to provide short and long term estimates for demand of the product, and optimal reorder quantities and delivery schedules, may be identified and determined.

Another advantage of the present invention is that a better estimation of product volumes and volume changes may be obtained by calculating the differential of the volume function.

Another advantage of the present invention is that a fuel access control system may be used to monitor dispensing activity from and control access to the fluid storage system.

A further advantage of the present invention is that all of the foregoing may be accomplished in a fully automated system that requires no human intervention, other than as an option available to the operator to enter quantities of material reportedly delivered for comparison with those computed.

Other features and advantages of the invention will become apparent from the following detailed description, and from the claims.

Brief Description of the Drawings

Description of the Preferred Embodiments

30 The method and apparatus described herein applies to UST's, AST's or any type of storage tank. The product stored in the tank may be any fluid, including dry particles that flow in the manner of a fluid.

~~WO 01/04586~~~~PCT/US00/18743~~

Fig. 1 shows a UST facility 10, illustrated as an automobile service station. Facility 10 includes a series of UST's 12, 14, 16 which may store the same or different types of liquid fuel product 18. Volumetric tank gauges 20, 22, 24 in each tank measure the height of product 18 in the tank. Submersible pumps 26, 28, 30 in each tank pump product 18 to one of dispensing pumps 32, 34 through piping lines 36, 38, 40. Alternately, facility 10 may be an AST facility with above-ground tank 1000, as shown in Fig. 11, or a facility with a partially above-ground tank 1010, as shown in Fig. 12.

Tank gauges 20, 22, 24 are mounted in tanks 12, 14, 16. The tank gauges may consist of or be based on magnetostrictive tank probes or other sensing technologies. In the case of magnetostrictive technology, two floats 42, 44 surround each probe, e.g., gauge 20 in tank 12. One float 42 floats on the upper surface of product 18 in tank 12, and the other float 44 floats on the interface of product 18 with any water or other foreign material collected at the bottom of tank 12. Tank gauge 20 determines the distance between floats 42, 44 to obtain the height of product 18 in tank 12. Tank gauge 20 also contains temperature sensors 46, 48, 50 spaced along its length to monitor the temperature of product 18 at various depth levels.

Each of the dispensing pumps 32, 34 consists of a totalizer or flow meter 52, 54 disposed in a housing 56, 58 to measure the volume of product 18 dispensed through hoses 60, 62 and nozzles 64, 66. To operate dispensing pump 32, nozzle 64 is removed from housing 56, which actuates dispensing pump 32 and causes product 18 to flow through hose 60 due to the pumping action of submersible pumps 26, 28, 30. A value stored in totalizer 52 is incremented as

WG 01/04586

~~PCTUS0045743~~

fuel is dispensed through hose 60. Upon completion of the transaction, nozzle 64 is replaced in housing 56, thereby turning off dispensing pump 32 and discontinuing the action of submersible pumps 26, 28, 30 and totalizer 52.

5 Transactions are recorded electronically by software in a sales recording device 71 connected to totalizers 52, 54 of dispensing pumps 32, 34. Totalizers 52, 54 in dispensing pumps 32, 34 are connected to sales recording device 71 by means of communications and power supply wires
10 78, 80.

Sales recording device 71 contains software capable of emulating the functions of a point of sale (POS) terminal associated with fuel sales made at facility 10. POS emulation software in sales recording device 71 functions on
15 the basis of read only commands to eliminate the possibility of conflict with control commands from a POS terminal employed by facility 10. Alternative data acquisition systems can result in destruction of credit card sales records, inadvertently shutting down the entire system,
20 and/or causing electrical interference in the pump links.

Tank gauges 20, 22, 24 are connected to a tank monitor 82 by means of communications and power supply wires 84, 86, 88 or communicate data through radio frequency transmission. Tank monitor 82 converts raw data obtained
25 from tank gauges 20, 22, 24 into a form usable by a computer.

A computer 70 contains a processor 72 capable of running various computer software applications and a memory 74. Tank monitor 82 and sales recording device 71 are
30 electrically connected to computer 70 to relay totalizer values, product height and temperature data to computer 70. Software executable by processor 72 of computer 70 is capable of querying tank monitor 82 and sales recording

device 71 to obtain measurement data at selected time intervals. The data is continuously evaluated as it is collected and is stored in memory 74 of computer 70 for later retrieval and detailed analysis. Alternatively, computer 70 may communicate with a host processor 90 at a remote location. The continuous evaluations or detailed analysis may then be performed by host processor 90, which may be faster or more efficient than computer 70.

As an example, computer 70 may be a personal computer or any other proprietary microprocessor-based unit. Computer 70 may capture data automatically through direct-connect serial interfaces with tank monitor 82 and sales recording device 71, or by manual operator keypad entry. Computer 70 communicates with equipment at facility 10 through four programmable serial communication ports, such as RS-232 communication ports.

Computer 70 may, e.g., store tank dimensions and product characteristics, and concurrent time and date data along with the measurement data. Computer 70 may be used to produce error and analysis reports as calculated by the software. It may also have alarm event-initiated capabilities, such as when a leak is detected in any of the tanks. Such a computer system can accommodate facility and customer specific requirements while maintaining complete compatibility with other system components.

The SIR method involves reconciling volume data obtained from tank monitor 82 and volume data obtained from sales records. Sales transactions may be detected in a number of ways, including an electronic signal emitted from totalizers 52, 54, by voltage sensing of control relays on pump dispensers 32, 34, or by observation of product removal using tank gauges 20, 22, 24.

It is essential that the measurements used to obtain these two types of data are made simultaneously. The SIR method of the present invention collects and analyzes observations of sales volumes and tank volumes which are derived simultaneously. Failure to collect both types of data simultaneously would bias estimates derived from separate volume measurements.

The SIR method properly accounts for the effects of temperature, pressure and specific gravity. In addition, product from two or more tanks may be blended, such as to achieve varying petroleum octane levels at pump dispensers 32, 34. When different fluid products are blended, the tanks are treated as one unit, and an additional parameter is introduced to determine the actual blend percentages.

Data concerning the physical characteristics of the tank configurations and the accuracy of the various gauges and metering devices is collected during installation and a set-up phase of operation of facility 10 to create a basis for subsequent statistical analysis. Information is then continuously collected so that the statistical analysis of SIR can be performed by computer 70 or host processor 90.

Several procedures are used either singly or in combination to obtain the volume observations. First, where the system configuration provides for determining whether hoses and dispensers associated with a given tank are active, the system is queried on a minute-by-minute basis, or on the basis of another predetermined time interval, to determine the status of the dispensers. When all of the dispensers are idle, the values from totalizers 52, 54, the tank volumes (i.e. product heights in the tanks) and temperatures are recorded.

Second, submersible pumps 26, 28, 30 are checked to determine on/off status. When it is determined that the

pumps are turned off, the values from totalizers 52, 54 are read, and tank volumes and temperatures are recorded.

Third, software algorithms used by computer 70 detect and measure leads and/or lags between the recording of sales events and corresponding gauge and meter readings. When leads or lags are encountered and constitute a physical characteristic of the data measurement and recording system, constrained optimization, rather than unconstrained optimization, may be used to determine parameter estimates. Lagrange multipliers are one example of such a constrained optimization method.

The method of the present invention is capable of providing dynamic monitoring of system performance. For example, the leak detection function is carried out continuously while normal operations, e.g., removals and deliveries, are taking place. To detect leaks dynamically, the software is programmed to detect when sales or delivery events occur and to calculate the volumes of product removed or added as a result of such activities. Thus, dynamic testing does not require that the system be dormant and addresses the entire system from the point of filling to the point of dispensing.

The SIR method of the present invention also distinguishes between one-time removals and continuous losses consistent with leakage. The integrity or leak-free status of the system is not assumed a priori. Instead, the individual and unique characteristic pattern induced by each form of error when viewed along the separate dimensions of time, product height and sales volume are used to identify and quantify the errors. The method may also be used to detect and quantify undocumented removals, e.g., theft or additions of product.

Further, the overall system is self diagnosing in that it determines from the data the maximum degrees of reliability and precision of which a particular operating configuration is capable at any given time, as well as the
5 degree of calibration accuracy.

In particular, product height in the tanks and temperature are measured continuously at, e.g., one-minute intervals. Height and gross volumes are converted to net
10 volumes at, e.g., 60°F or 15°C, using the algorithms described below. Sales recorded by the totalizers 52, 54 are extracted and stored in memory 74 at times coincident with readings from tank gauges 20, 22, 24. If the
15 dispensing system is capable of transmitting a signal indicating whether or not any or all individual hoses are active, that information is also stored in memory 74
coincident with taking gauge and meter readings.

The method of the present invention is designed to achieve the maximum accuracy possible within the limitations imposed by the inherent random and irreducible noise in the
20 various measuring devices incorporated. It utilizes multiple measurements over extended time periods to identify and quantify systematic and repeatable effects in the instrumentation and thereby correct for such effects using the known physical characteristics of the devices. The
25 system makes no a priori assumptions as to the accuracy of the devices used to measure product volume in the tank, to measure volumes removed, or as to the accuracy of volumes reported to have been delivered into the system.

The resulting volumetric calculations are
30 independent of the physical characteristics of the tank configuration and the various measuring devices which may be incorporated in the system. The results do not rely on input entered externally by the operator or from diagnostics

internal to the measuring devices used. Instead, the output produced by the software which analyzes the measured data depends only on the patterns induced in inventory data produced by the tank gauges and measuring devices and, in particular, the cumulative variances that result when the various input values are combined.

Various error patterns which the measuring devices can induce and the effects of temperature, tank geometry, and orientation on cumulative variances are derived from empirical analysis of real-world inventory data. The system's software synthesizes the output measurements of the various devices based on known characteristics derived from the empirical data. Thus, the software is capable of identifying measurement errors caused by the measuring devices and simultaneously compensating for the effects of those errors.

Gauges can be systematically inaccurate in two ways. The height of the product in the tank can be incorrect, and the height to volume conversion algorithms may not reflect accurately the true dimensions of the tank or its orientation in the ground. The latter may be the result of incorrect measurements or an inappropriate conversion algorithm.

The presence of such systematic effects and their nature may be established by examining the pattern of inventory variances as a function of product height. Errors of this kind induce patterns which repeat themselves as the tank is filled and emptied. If the tank length is incorrect, a linear pattern is induced. If product height is in error, a curvilinear pattern results reflecting the varying volumes in different cross sections of a cylindrical tank. Tilt along the length of the tank induces a sinusoidal pattern symmetrical about the mid-height of the

WO 01/04586

PCT/US00/18743-

tank. Absent such errors, the pattern will be purely random, reflecting only the inherent noise of the measuring devices. The absence of randomness and the presence of a systematic pattern serves to identify the presence of systematic error. The pattern of a departure from random and its extent determines the source and extent of the systematic effects and the means necessary to correct them.

Dispensing errors, unlike volume measuring errors, are independent of product height, but are sensitive to the volume of product dispensed. The nature and extent of dispensing errors can be established by examining inventory variances as a function of sales volume. As in the case of volume measurements, in the absence of systematic errors, variances as a function of sales volume will be random. The form and extent of departures from randomness serve to determine the source and extent of the errors and provide for their removal.

Leakage from the system creates a continuous downward trend in the cumulative variance when viewed as a function of time. By contrast, one-time additions and removals of product cause significant upward or downward translations of the cumulative variance which remain permanently in the record and do not introduce a continuous trend. Leakage is distinguishable from tank gauging errors when viewed as a function of product height because the pattern does not repeat as the tank is filled and emptied. If product is leaking from the system, a series of parallel translations in the cumulative variance is generated, each shifted by the volume of product lost between deliveries.

The accuracy of measurements taken from the various components of the system determines the accuracy achievable in any one individual observation. Since the leak rate is computed from a series of successive observations, however,

the minimum detectable leak rate can be reduced to any desired magnitude by increasing the number of successive observations recorded. Thus, the system can serve as a final verification for leakage indications obtained by other methods.

At the conclusion of an initial set up period of data collection including one or more delivery and sales cycles, the collected measurement data is analyzed by regression analysis. The initial set-up regression is used to derive tank dimensions and orientation, individual meter calibrations and secular trends. A confidence level value p is computed at the .01 level of significance to determine the minimum leak rate detectable by the system, and the residual variance is computed to provide the current noise level of the system.

The regression is performed according to the following equation:

$$st_i(R, L, T) = a - \sum_{j=1}^i \sum_{k=1}^n \alpha_k Sa_{kj} + \sum_{j=1}^i D_j - Et_i Ls + \sum_{j=1}^m B_j I_{ij} \quad (1)$$

where:

$st_i(R, L, T)$ = Volume in gallons derived from the i th gauge reading in inches in a cylindrical tank with or without hemispherical end caps with radius R , length L , and tilt over its length of T inches.

a = Initial inventory in gallons, which is to be estimated.

Sa_{kj} = Sales volume recorded on the k th totalizer.

α_k = Fraction of sales volume recorded on the k th totalizer actually removed from the tank, which is to be estimated.

D_j = Volume of the j th delivery.

E_{t_i} = Elapsed time since initiation until the i th gauge reading is recorded.

L_s = Constant gain or loss in product per unit of time.

5 B_j = Volume of product added (e.g. delivery) or removed during some discrete time interval prior to or during observation period j .

$$I_{ij} = \begin{cases} 0 & \text{if } j < i \\ 1 & \text{if } j \geq i \end{cases}$$

10 All of the parameters are estimated simultaneously using least square estimation procedures. The R and T parameters are derived numerically, but the other parameters are derived analytically.

15 Further, all of the parameters, including the initial inventory, are estimated simultaneously. The initial volume must be estimated from all succeeding data, even if the tank is initially empty, otherwise the initial gauge reading and its conversion to gallons is assigned a credibility not assumed for all succeeding readings. Also, in a great majority of applications, the initial inventory in an already existing and operating system is not
20 accurately known.

Initial inventory estimation is vital in determining the geometry of the tank. When tank geometry, tank orientation, or tank product height measurement depart from the values obtained from nominal sources, all gauge and
25 meter measurements are affected. It is practically impossible to detect the errors induced in the gauge measurements and correct for them unless the estimation of the initial inventory is made coincident with the estimation of the values of the other parameters.

The estimate of the parameters are based on the totality of the data collected. This means, e.g., that the estimate of leak rate L_s is determined from a linear trend including all of the data collected, not merely at one end of the reconciliation period. Likewise, estimates of tank dimensions and orientation are derived from their overall contribution to reduction in residual variance, as opposed to a sale by sale analysis of tank segments.

The volume $st_1(R, L, T)$ is derived from the product height measurement by multiplying the constant area of tank segments of height h (in inches) by tank length L . The volume in gallons of product in a horizontal cylindrical tank of radius R is given by:

$$Vol = \frac{L}{231} \left[R^2 \cos^{-1} \left(\frac{R-h}{R} \right) - (R-h)(2Rh - h^2)^{\frac{1}{2}} \right]$$

In the case of a tilted tank, the area of the segments varies with position along the length of the tilted tank, and the volume is determined by integrating over the length L . Such integration does not result in a closed form because the cross sections are not circular, and a numerical integration would severely limit the frequency of observations. Instead, in this application the tank is treated as lying horizontally and the product is considered tilted, to derive an equivalent volume. This integration yields the closed form:

$$Vol = \frac{R^3}{231} \left[(z-1) \sin^{-1} (2z - z^2)^{\frac{1}{2}} - \frac{1}{3} (2z - z^2)^{\frac{3}{2}} \right] \frac{hu}{R} \frac{hl}{R}$$

The integrand is evaluated between the normalized product heights in inches, hu/R and hl/R , at the lower and higher ends of the tilted tank, respectively. It is standard

industry practice to install tanks on an incline to divert water and sludge away from the submersible pumps.

5 Tank tilt is identified from the pattern it induces in the record of cumulative variances as a function of product height. It is compensated for by fitting the correct mathematical form for height to volume conversions in a tilted tank to the cumulative variance calculated by the method of least squares. This is done simultaneously with estimation of the initial inventory.

10 Tank length L and radius R are established by equating the first partial derivatives of the sum of squared cumulative variance with respect to length and radius and determining the values which minimize the sum of squared variances. Simultaneous estimation of initial inventory is
15 also required when estimating tank length L and radius R .

Errors in measurement of the product height h in the tank are characterized by curvilinear patterns induced by height to volume conversions in the cumulative variance for a cylindrical container when heights are transposed upward
20 or downward. Such errors also are compensated for by minimizing the sum of squared cumulative variances with respect to increments or decrements to measured product height. This estimation also requires simultaneous estimation of the initial inventory of the tank.

25 In general, the accuracy of the estimates of the tank dimensions, tank orientation and height measurements is confirmed by observing that the cumulative variances of each derived value as a function of nominal product height are random and display no systematic influence or effects.

30 Dispenser totalizer calibration is continuously monitored and evaluated by minimizing the sum of squared cumulative variances with respect to multiplicative constants associated with individual reported cumulative

sales volumes from all pump dispensers associated with a particular tank system. This eliminates the need for manual verification of meter calibration.

5 In particular, gauge performance is continuously monitored to identify gauge malfunctions or degradation in gauge performance. Monitoring of gauge performance is independent of diagnostics which are internal to the measuring device. Diagnoses of problems are based only on their impact on the cumulative inventory variances which are
10 continuously monitored by the software.

If the gauge fails to record changes in product height when the dispensers register sales, an increase in cumulative variances approximately equal to sales volume is observed; this effect can be identified by the monitoring
15 software and a warning of gauge malfunction generated to the operator.

However, observation of the gauge registering product height change, but with a time lag after sales are recorded, may be a feature of normal gauge performance.
20 Such normal gauge performance is identified by repeated positive increments in cumulative variances as sales are completed with subsequent return of the cumulative variance to normal bounds. When such gauge function is determined to be the normal operating characteristic of a particular
25 system, constrained optimization with lagged variables is introduced into the software. Otherwise, the gauge's performance is reported as a malfunction.

Finally, temperatures in the tank are monitored to detect changes that are excessive for the time intervals
30 between observations. Erratic temperature readings are deleted, and may indicate gauge malfunction.

The software computes actual, rather than nominal, delivered quantities and requires no input by the system

operator. The operator may choose to input into the system the nominal delivery quantity indicated by the delivery invoice, along with the temperature and coefficient of expansion of the product at the point of pick-up. The software will then compute overages or shortages between the nominal and actual quantities delivered, as well as the overages or shortages caused by temperature-induced variations in the transport of the product to the facility and in the subsequent mixing of the delivered product with that resident in the tank.

Delivery is identified by the software when a positive cumulative variance is observed which exceeds the system noise level and is not succeeded by a return to normal variance bounds. Delivered quantities are computed by estimating the volume increases they induce in multiple, successive observations. The required number of successive observations is determined as that sufficient to generate a confidence width which is within a predetermined tolerance. The system of the present invention is capable of accounting for sales conducted during delivery and for noise introduced by post delivery turbulence in the tank.

One-time unaccounted for removals or additions to the tank are computed in the same manner. Deliveries are distinguished from such events by computing the rate of input, which in the case of normal gravity delivery should exceed 100 gallons per minute. Other modes of delivery, e.g. pipeline delivery into above ground tanks, are identified by incorporating their known delivery rates.

Leakage from the system is identified by a continuous linear negative trend in the data which exceeds the computed minimum detectable leak rate after all of the various error phenomena described above have been identified and compensated for. This calculation deals with the

totality of the data obtained by constantly monitoring known removals and is not restricted to observations made only when the system is dormant. It is also independent of any single data reconciliation calculation in that trends throughout all of the data are evaluated.

All calculations concerning volumes are made on the basis of net volumes, according to the following definitions:

$$\text{Net Volume in Tank} = \text{Gauge Volume} (1 - (t-60)CE)$$

where:

t = Measured temperature in degrees Fahrenheit (if centigrade, the term in parentheses becomes (t-15)).

CE = Coefficient of expansion.

and

$$\text{Net Sales Volume} = \text{Metered Sale} (1 - (\frac{t_1 + t_2}{2} - 60) CE)$$

where t_1 and t_2 are temperatures measured by the tank gauge at the beginning and ending of a sale transaction, respectively. Deliveries are computed in net gallons, but are converted to gross quantities if required, based on external information input by the system operator, as follows:

GT = Gross gallons on invoice at the originating terminal.

NT = Net gallons on invoice at the terminal.

tT = Temperature at the terminal.

CE = Coefficient of expansion.

The program also records:

WO 91/04536

PCT/US90/18743-

t_A = Ambient temperature in the tank prior to delivery.

t_F = Temperature in the tank at the conclusion of delivery.

5 The following value is computed:

t_S = Temperature of the product in the delivery vehicle at the facility at the beginning of delivery.

$$= t_F + \frac{NVA}{NVD} (t_F - t_A)$$

10

where:

NVD = Actual net volume delivered, previously computed.

NVA = Net volume in the storage tank at the start of delivery.

15

NS = Net overage(+) (underage (-)) in delivery.

$$= NT - NVD$$

GVD = Gross volume delivered.

$$= NVD (1 + (t_F - 60) CE)$$

GVS = Gross volume in the transport vehicle at the facility prior to delivery.

20

$$= NVD (1 + (t_S - 60) CE)$$

GSM = Shrinkage due to mixing in the tank.

$$= GVS - GVD$$

GVT = Actual gross volume in the transport vehicle at the facility.

25

$$= NVD (1 + (t_T - 60) CE)$$

GST = Shrinkage during transit to the facility.

$$= GVT - GVS$$

GOS = Gross overage(+) (underage(-)) adjusted
for temperature effects.

$$= GT - GVD + GST + GSM$$

Calculations of volumes actually delivered are based
5 on multiple observations of the balance of measured tank
volumes and cumulative sales. This method requires frequent
simultaneous observations of sales and in-tank volumes (i.e.
product heights) and temperatures.

The volume of product in a tank is derived by
10 measuring the height of the product and using the geometry
of the tank, which is assumed to be known, to compute the
corresponding volume. In many instances, tank dimensions
vary substantially from assumed design dimensions.
Regulatory specifications permit up to 10% variation in
15 length and diameter of cylindrical tanks.

Tank orientation can also cause complications in the
calculations. The volume corresponding to a measured height
varies substantially when the tank is tilted away from
horizontal or rolled away from vertical.

20 Further, tanks may also fail to conform to a known
geometry either through faulty manufacture or installation,
or may suffer significant deformation during the course of
operations. For example, many fiberglass tanks sag or bend
along their length.

25 In addition, installed tanks are typically
inaccessible, and difficult to measure. Thus, it is
necessary to confirm the accuracy of height to volume
conversions from generated inventory data and to identify
and correct discrepancies where they exist.

30 The foregoing problems are compounded when two or
more tanks are manifolded together. Manifolded tanks are
joined together by piping systems and serve common

dispensers. Thus, sales quantities from manifolded tanks constitute withdrawals from all tanks in the manifolded system, but not necessarily in equal quantities. Product heights typically vary from tank to tank, but tank geometries, dimensions and orientation may also vary so that a procedure for correcting height to volume conversion errors for a single tank will not apply.

The different factors which influence inventory data manifest themselves in distinct ways which facilitate their identification and correction. These factors are most easily identified by examination of their effects on cumulative departures of actual measured inventory from a theoretical or book value when viewed across a variety of dimensions. In particular, one-time undocumented physical additions or removals of product, e.g. over or under deliveries and pilferage, are evidenced by an addition or subtraction of a constant quantity from the cumulative variance at the time of occurrence and all subsequent observations. Continuous loss of product accumulating over time, e.g. leakage, is evidenced by a loss trend over time. Continuous loss of product varying proportionally with sales value, such a line leak or meter miscalibration, may be determined by identifying a constant negative trend that is cumulative only over periods where delivery lines are pressurized.

A pattern of gains or losses, or both, recurring cyclically as the tank is successively filled and emptied with no long term gain or loss of product, is the pattern associated with height to volume conversion error. The pattern is cyclical because the error source is identical in each cycle as the tank is filled or emptied. It is distinguishable from the other patterns in that it retraces

the same path without the translation which would occur if physical loss or gain of product were taking place.

This problem is most readily diagnosed by analyzing cumulative variance as a function of product height. If the
5 variances are random with no evidence of systematic effects, height to volume conversions may be assumed to be correct. If not, the form of the induced pattern indicates the nature of the conversion error. Thus, an error in tank length induces a linear pattern, an error in tank tilt induces a
10 sinusoidal pattern, and a constant error in tank height measurement induces an arc-like pattern. When other sources of loss or gain are present, the conversion error patterns remain, but are translated in each succeeding filling/emptying cycle to reflect the physical loss of
15 product which has occurred during that cycle. Thus, confusion between conversion errors and other effects can be eliminated.

Sales readings and product height measurements must be made simultaneously. Since the number of observations in
20 any one sales cycle is typically too few to generate a conversion table of sufficient detail to be of practical use, subsequent sales cycles and their corresponding deliveries must be incorporated. If, however, deliveries are unmetered and are used to approximate the volume (as is
25 the standard industry practice), significant inconsistencies are introduced. If an overage or shortage occurs during delivery, then all subsequent sales volumes correspond to tank cross sections which have been shifted upward or
30 downward from their predecessors. Averaging or statistical treatment cannot overcome this deficiency since there is no means of knowing without metering whether, by how much, and in what direction the data has been shifted.

The procedure of the present invention may include determining if height to volume conversion error is a problem. If the error is a problem, then the system must determine the nature of the problem, e.g. tank dimensions, tank orientation, height measurement or unknown tank geometry, and whether the conversion problem is compounded by other gains and losses. If leakage is suspected, an on-site leak detection investigation is undertaken. In no leakage is indicated, and one or all of tank dimensions, tank orientation and height measurement are problems, new conversion factors are calculated and confirmed using the diagnostic procedures described herein.

If unknown tank geometry or manifolded systems are encountered, the exact current percentage of metered sales actually dispensed from each dispenser is determined by physical measurement. A high order polynomial using a variable of measured product height is used to convert height to volume. The parameters of the polynomial are derived from the differences between measured product height corresponding to the beginning and ending of sales events which do not overlap deliveries.

For a single tank, actual dispensed quantities are regressed using a polynomial based on the differences in measured product height before and after individual sales, subject to the constraint that when the polynomial is evaluated at a height equal to tank diameter, the result is the total tank volume. Observations which include delivery events are discarded.

$$ASale_i = a_1(h_{i-1} - h_i) + a_2(h_{i-1}^2 - h_i^2) + \dots + a_n(h_{i-1}^n - h_i^n)$$

$$Vol = a_1d + a_2d^2 + \dots + a_nd^n$$

A fifth order polynomial has proven adequate in most cases. Residual analysis may be used to determine adequacy of the polynomial in the presence of severe tank distortions, and higher order polynomials may be introduced as necessary. The number of observations required is determined by estimating a confidence bound around the resulting polynomial with a width adequate for the desired resolution. Thus,

- ASale_i = Actual dispensed volume in period i.
- 10 h_i = Product height upon conclusion of ASale_i.
- h_{i-1} = Product height prior to commencement of ASale_i, and after completion of ASale_{i-1}.
- 15 d = Diameter of tank.
- Vol = Total volume of tank.

The converted volume for height h is then given by:

$$\text{Vol (h)} = a_1 h + a_2 h^2 + \dots + a_n h^n$$

The omission of a constant term in the regression implies that

$$\text{Vol (h)} = 0 \text{ when } h = 0$$

This ensures that the polynomial derived from the height differences is well defined.

For manifolded systems, actual sales are regressed simultaneously on individual polynomials based on the various height differences in the several tanks which correspond to a particular sales volume, subject to the constraint that each polynomial evaluated at the corresponding tank diameter yields the total volume of that tank.

~~WO 01/04586~~~~PCT/US00/18743~~

$$\begin{aligned}
 ASale_i &= a_{11}(h_{i-11} - h_{i1}) + a_{21}(h_{i-12}^2 - h_{i1}^2) \\
 &+ \dots + a_{n1}(h_{i-1n}^n - h_{i1}^n) \\
 &+ a_{12}(h_{i-12} - h_{i2}) + a_{22}(h_{i-12}^2 - h_{i2}^2) \\
 &+ \dots + a_{n2}(h_{i-12}^n - h_{i2}^n) + \dots \\
 &+ a_{1m}(h_{i-1m} - h_{im}) + a_{2m}(h_{i-1m}^2 - h_{im}^2) \\
 &+ \dots + a_{nm}(h_{i-1m}^n - h_{im}^n)
 \end{aligned}$$

where:

$ASale_i$ = Actual Sales volume in period i .

h_{i-1j} = Height of product in tank j after completion of $ASale_{i-1}$ and prior to commencing $ASale_i$.

j = 1, 2, . . . m

h_{ij} = Height of product in tank j after completion of $ASale_i$.

m = Number of tanks manifolded.

Volume conversion for the m measured heights, h_1, h_2, \dots, h_m in the total system is:

$$Vol(h_1, h_2, \dots, h_m) = \sum_{i=1}^m \sum_{j=1}^n a_{ji} h_i^j$$

where:

h_i = Height of product measured in the i th tank in the manifold.

Delivery inaccuracies have no impact on this calculation since all observations made during deliveries are discarded. Height changes are related only to the corresponding volumes dispensed.

Prior determination of actual quantities dispensed, as opposed to metered quantities, ensures that the only

remaining source of error is random measurement error. Regression is designed to accommodate random error of this kind and to facilitate inferences when errors are present.

An alternative method of estimating volume of product based on product height in single or manifolded tanks involves determining a volume function by integrating a differential of the volume function. The total differential of the volume function is estimated using one of several procedures, e.g., least squares estimation. For example, for a manifolded system of storage tanks, if

$$Sa_i = V(h_{1i}, h_{2i}, \dots, h_{mi}) - V(h_{1i+1}, h_{2i+1}, \dots, h_{mi+1})$$

where Sa_i is the measured volume change associated with measured changes in product height during a dispensing event from the manifolded tanks, then

$$\begin{aligned} Sa_i &= V(h_{1i}, h_{2i}, \dots, h_{mi}) - V(h_{1i+1}, h_{2i+1}, \dots, h_{mi+1}) \\ &= V_1(h_{1i}, h_{2i}, \dots, h_{mi})(h_{1i} - h_{1i+1}) + V_2(h_{1i}, h_{2i}, \dots, h_{mi})(h_{2i} - h_{2i+1}) + \\ &\quad + \dots + V_m(h_{1i}, h_{2i}, \dots, h_{mi})(h_{mi} - h_{mi+1}) \end{aligned}$$

where $V_j(h_{1i}, \dots, h_{mi})$ is the partial derivative of the volume function with respect to h_j , the height of the fluid in the j^{th} tank. The least squares technique provides maximum likelihood estimates because measurement errors occurring in tank gauges 20, 22, 24 have been established to be normally distributed.

A differential function for a volume function having any functional form may be estimated in this manner. For example, a high order polynomial may be used and constrained to have a preset volume at a maximum height, zero volume for zero height in all tanks and/or zero value of the first derivative at maximum height and at zero height.

~~WO 01/04586~~~~PCT/US00/48743~~

For example, if

h_{ij} = product height in tank i at the completion of sale j and prior to the start of sale $j+1$,

5 Sa_k = volume dispensed in sale k ,

and the volume function is an r^{th} order polynomial in the form

$$\text{Vol}(h_1, h_2, \dots, h_m) = \sum_{i=1}^m \sum_{j=2}^r a_{ij} h_i^j$$

then

$$Sa_k = \sum_{i=1}^m \sum_{j=1}^{r-1} (j+1) a_{ij} h_{ik}^j (h_{i,k-1} - h_{i,k})$$

10 where the linear term of the polynomial is omitted to provide a zero derivative at $h=0$. Then, the following equation may be minimized

$$\sum_k (Sa_k - \sum_{i=1}^m \sum_{j=1}^{r-1} (j+1) a_{ij} h_{ik}^j (h_{i,k-1} - h_{i,k}))^2$$

subject to

$$\sum_{j=1}^{r-1} (j+1) a_{ij} h_{i,j}^{\text{max}} = 0$$

and

$$\sum_{j=2}^r a_{ij} h_{i,j}^{\text{max}} = \text{Volmax}_i$$

for

$$i=1, 2, \dots, m$$

where $h_{max,i}$ is the maximum product height in tank i , $Vol_{max,i}$ is the preset maximum volume in tank i , and m is the number of tanks in the manifolded system.

The foregoing equation works well for $m=1$. For $m>1$, a further constraint is required to ensure upward concavity of the individual volume functions near zero volume. This is accomplished by constraining the second partial derivatives of the individual volume functions to be positive at zero volume. In the case of polynomial functions and tanks with equal radii, this reduces to the constraint $a_{1,1}=a_{2,1}=\dots=a_{m,1}$.

Alternatively, the volume function may take the form

$$V(h) = \frac{e^{f(h)}}{1+e^{f(h)}}$$

where $f(h)$ is a function of the height h . The derivative of $V(h)$ is

$$V'(h) = \frac{e^{f(h)} f'(h)}{(1+e^{f(h)})^2}$$

Numerical minimization may be used to estimate this derivative function. An advantage of a function in the form of $V'(h)$ is that it asymptotically approaches zero (0) near $h=0$ and one (1) near the maximum height.

Determining the volume function by integrating an estimated derivative of the volume function has many advantages. For example, the data used to estimate the derivative consists of discrete measurements of dispensed volumes and corresponding product height changes, which avoids introducing ambiguities and errors due to inaccurate calculations of deliveries of the product. The data does not need to be sequential, and data for periods during deliveries and post delivery turbulence may be discarded.

Because the only error sources are in the metering devices (for which calibration may be determined as described herein) and random errors of height measurement (the magnitude of which may be determined as described herein) the error resulting from the height to volume conversion may be contained within acceptable limits. Further, the volume function derivative may be estimated accurately because the system can collect a large number of data points, which may be stored in a compressed format as described below, and because the system avoids delivery calculation errors. As in the case of calculating the volume of product in a single tank, the sales, volume and tank height measurements must take place simultaneously, the calibration of individual meters must be monitored and recorded, and a large volume of data must be collected and recorded.

With respect to temperature, the temperature of product delivered into a tank system almost invariably differs from the temperature of the product already in the tank. Its addition has the effect of expanding or contracting the volume of the combined product. This change in volume can create the appearance of incorrect dimensions of the height to volume conversion, appear as leakage where none exists, or it can mask the existence of actual leakage.

It is therefore preferable, and frequently essential, that all volumes, sales, deliveries and product in storage be converted to a common temperature prior to analysis. Typically 60°F (15°C) is chosen as the standard. The conversion is accomplished as follows:

$$\text{Net Volume} = \text{Gross Volume} (1 - (t-60)CE)$$

where:

t = Measured product temperature in degrees Fahrenheit.

CE = Coefficient of expansion.

As above, all calculations are in net gallons of product.

A complication to the calculation may occur if the tank gauges 20, 22, 24 used to measure product volume are designed for static or dormant mode tank testing. Such tank gauges detect leakage when the tank is taken out of service. In this case, product volume changes due to temperature changes during the course of a test must be accounted for.

Further, as shown in Fig. 1, temperature sensors 46, 48, 50 are located at different heights in tank 12. If the level of product falls below a given temperature sensor, the corresponding weighted temperature measurement is dropped from the average temperature calculation, and a temperature jump and corresponding volume change may be observed when the net volume is calculated using the new weighted average of temperatures. If uncorrected, such repeated jumps in the data would preclude further analysis of the data for leak detection or the generation of height to volume conversions.

The system of the present invention may be used to overcome these temperature related problems. Using the following definition,

$NDB_N =$ The net cumulative variance in the inventory data at observation N.

then,

$$NDB_N = a(1 - (t_0 - 60)CE)$$

$$- \sum_{i=1}^N S a_i (1 - (t_i - 60)CE) \\ - V_N (1 - (t_N - 60)CE)$$

where:

- a = Gross initial inventory.
 t_0 = Temperature of initial product volume.
 t_i = Temperature of product at observation i .
 Sa_i = Gross volume sold in period i .
 V_N = Measured gross volume in tank at period N .
 CE = Coefficient of expansion.

Absent random error or leakage, and assuming no deliveries of product, then

$$NDB_N \approx 0$$

and

$$a(1 - (t_0 - 60)CE)$$

$$- \sum_{i=1}^N Sa_i (1 - (t_i - 60)CE)$$

$$= V_N (1 - (t_N - 60)CE)$$

Therefore, if a temperature jump to temperature t^* occurs at an observation $N + 1$, then

$$\begin{aligned}
 NDB_{N+1} &= V_N(1 - (t_N - 60)CE) \\
 &\quad - Sa_{N+1} (1 - (t^* - 60)CE) \\
 &\quad - V_{N+1} (1 - (t^* - 60)CE) \\
 &= V_N(1 - (t_N - 60)CE) \\
 &\quad - Sa_{N+1} (1 - (t^* - 60)CE) \\
 &\quad - (V_N - Sa_{N+1}) (1 - (t^* - 60)CE) \\
 &= V_N(t^* - t_N)CE
 \end{aligned}$$

When this final quantity NDB_{n+1} is added to the volume where the transition occurs between temperature sensors, and all subsequent volumes, the effect of the transition is eliminated, and analysis proceeds as it would where individual temperature readings are available.

A large number of variables must be estimated by the software to implement the SIR system of the present invention. For example, as many as forty hoses and independent totalizers per tank system, as well as deliveries numbering four or more per day must be accommodated. Thus, a very large volume of data must be accumulated, encompassing a substantial spread of sales volumes from each totalizer for both the set-up analysis and subsequent routine monitoring. To accommodate this volume of data within current or conceivable future practical computer memory capabilities, the algorithm implemented by the software utilizes a matrix formulation which invokes the property of a sufficient statistic to reduce the memory requirement.

The calculations used to determine the various error, loss trend and delivery estimates have the form:

$$B = (x^T x)^{-1} x^T y$$

$$MSE = \frac{(y - xB)^T (y - xB)}{m+1}$$

$$S^2 = (x^T x)^{-1} MSE$$

where:

B = Column vector of m parameters to be estimated.

x = Matrix of parameter coefficients.

y = Column vector of independent variables.

MSE = Mean squared error.

S^2 = Variance covariance matrix of parameter estimates.

The values contained in vector y comprise tank gauge readings. The entries in matrix x are measured sales volumes, time, and other constant values. The parameters of vector B which are to be evaluated include the initial volume of the system and subsequent volume changes, including delivery amounts.

For example, if observations are recorded every minute, as many as 1440 rows in the x matrix and the y vector may be recorded. It would clearly be impractical to accumulate and store data in that form over an extended period of time. Instead, data compression techniques are applied so that only a manageable amount of data need be stored.

The algorithm utilizes the property that if an $n \times m$ matrix A is partitioned into two submatrices, B and C , where B is an $i \times m$ matrix and C is a $j \times m$ matrix, such that $i + j = n$, then

$$C^T C = A^T A + B^T B$$

For example,

if $C = \begin{bmatrix} 1 & 2 \\ 1 & 2 \\ 2 & 1 \\ 1 & 2 \end{bmatrix}$ then $A = \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix}$ and $B = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$

$$A^T A = \begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ 4 & 8 \end{bmatrix}$$

$$B^T B = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ 4 & 5 \end{bmatrix}$$

$$\text{Thus, } A^T A + B^T B = \begin{bmatrix} 7 & 8 \\ 8 & 13 \end{bmatrix}$$

5

$$C^T C = \begin{bmatrix} 1 & 1 & 2 & 1 \\ 2 & 2 & 1 & 2 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 1 & 2 \\ 2 & 1 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 7 & 8 \\ 8 & 13 \end{bmatrix}$$

At the conclusion of each 24 hour or other period,
 10 only $x^T x$ and $x^T y$ are computed and stored. The matrix x has
 the form of a square $n \times n$ matrix. Further, the aggregates
 of observations for different periods are additive, since
 two square matrices having $n \times n$ dimensions may be added.
 Thus the total data storage requirement for each period is
 15 determined only by the square of the number of parameters of
 interest.

The system is able to accommodate virtually
 unlimited numbers of observations by this method of data
 compression. Without this capability, the system would not
 20 have the storage capacity to accurately and simultaneously
 estimate the numbers of parameters which are required to
 perform a statistically significant calculation. This data
 compression method also allows for processing the data at
 the facility or for transmitting the data to a host computer
 25 for periodic analysis. Figs. 2, 3 and 4 show the Mathcad
 computer code used to perform the data compression
 algorithm.

Furthermore, $(x^T x)^{-1} x^T y$ is a complete and sufficient
 statistic for B . No statistically useful information is

WO 01/04586

lost in the compression. The overall procedure is, therefore, unlimited by memory. The only limitation remaining is the precision available in the computer system used.

5 The software performs SIR analysis, including inventory estimation and leak detection, using the above equation in the following form:

$$\begin{aligned} x &= [1_{\text{range}}, (-1)(T_{\text{range}}), (-1)(S_{\text{range}}) \langle \text{meters} \rangle] \\ y &= (Stk_{\text{range}}) - (CD_{\text{range}}) \end{aligned}$$

10 where:

$$\begin{aligned} \text{range} &= 1 \dots (\text{number of observations}) \\ \text{meters} &= 1 \dots (\text{number of dispensers}) \end{aligned}$$

and

$$\begin{aligned} 1_{\text{range}} &= \text{Column of 1's.} \\ 15 \quad T_{\text{range}} &= \text{Cumulative time in minutes.} \end{aligned}$$

$$(S_{\text{range}}) \langle \text{meters} \rangle = \text{Cumulative sales for an individual dispenser in gallons.}$$

$$CD_{\text{range}} = \text{Cumulative deliveries.}$$

$$20 \quad Stk_{\text{range}} = \text{Tank stick reading in gallons.}$$

To estimate the initial inventory, the matrix x includes a column of unitary values. To estimate loss trends, the matrix x includes a column containing cumulative times of measurement and cumulative sales. The values of B , MSE and S^2 are then calculated, producing the following

25 result for the vector B :

$$\begin{aligned} B_1 &= \text{Estimated initial inventory.} \\ B_2 &= \text{Loss trend.} \\ B_{2+\text{meters}} &= \text{Individual meter error.} \end{aligned}$$

30 B is the vector containing the parameter estimates, namely beginning inventory, meter calibrations and loss rate. The loss rate estimate is in the second row ($n=2$).

S^2 is the variance covariance matrix of the parameter estimates. Thus, $S_{22} = (S^2_{22})^{1/2}$ is the standard deviation of the loss rate estimate. Finally, the minimal detectable leak is defined as $t_\alpha S_{22}$, where t_α is the $(1-\alpha)$ percentile of the Student's t distribution.

The software performs delivery calculations using the equation in the following form:

$$x = [l_{\text{range}}, (T_{\text{range}})(-1), (S_{\text{range}})(-1), (D_{\text{range}})1]$$

$$y = (\text{Stk}_{\text{range}})$$

where:

$$\text{range} = 1 \dots (\text{number of records})$$

and

$$l_{\text{range}} = \text{Column of 1's.}$$

$$T_{\text{range}} = \text{Cumulative time in minutes.}$$

$$S_{\text{range}} = \text{Cumulative sales in gallons.}$$

$$D_{\text{range}} = 0 \text{ where } T_{\text{range}} \text{ is less than delivery time}$$

and

$$1 \text{ where } T_{\text{range}} \text{ is greater than or equal to delivery time.}$$

$$\text{Stk}_{\text{range}} = \text{Tank stick reading in gallons.}$$

The values of B , MSE and S^2 are then calculated, producing the following result for the vector B :

$$B_1 = \text{Estimated initial inventory.}$$

$$B_2 = \text{Loss trend.}$$

$$B_3 = \text{Meter error.}$$

$$B_4 = \text{Estimated delivery amount.}$$

S^2 is the variance covariance matrix of the estimates. Thus, $S_{44} = (S^2_{44})^{1/2}$ is the standard deviation of B_4 , the delivery volume estimate. The delivery tolerance is $B_4 \pm t_\alpha S_{44}$, where t_α is the $(1-\alpha)$ percentile of the Student's t

distribution. Delivery tolerances can be reduced to any desired value by increasing the number of observations used in the calculation.

5 The SIR analysis used by the method of the present invention involves computing and comparing cumulative variances. When the initial set-up is complete, computed trend and meter calibrations are used to project forward an expected cumulative variance, that is, the expected value of the difference between gauge readings and computed
10 inventory. Actual cumulative variances are then computed from all subsequent gauge and meter readings and compared to the expected variance.

Figs. 5, 6 and 7 show the routine operation procedure 100 followed by the software to perform this
15 analysis. Data from the set-up of the system and the most recent analysis is entered into the program at step 102. The data entered includes the tank type, tank dimensions, tank tilt, meter calibrations, mean square error and calculated trends. At step 104, three variables established
20 as counters, Counter1, Counter2, and Counter3, are set at zero. The measurement data from the system itself is entered at step 106, namely the readings from the dispenser totalizers, the product height and the product temperature.

The software computes the gross volume of the product, the most recent gross volume and the sales as
25 measured by the individual dispensers at step 108. The software further manipulates the data at step 110 by converting all gross volumes to net volumes, computing observation to observation variance, and computing
30 cumulative variance. The sign of the cumulative variance is recorded at step 112.

The program proceeds on the basis of the cumulative variance and the value of Counter1 in steps 114, 120, 124,

128, 132, 136 and 140. Depending on the cumulative variance and the value of Counter1, the program analyzes the collected data at step 118 if it is a final observation (step 116), deletes the collected data (steps 122 and 134), performs the analysis for a delivery (step 126) (see below), or reads new data (steps 116, 122, 130, 134, 138 and 142) upon updating the value of Counter1 and other computational variables (i.e. index, sign index and sign). In some cases, collected data is deleted (steps 122 and 134).

Upon computing the loss rate at step 144, the program reads new data at step 146 if the loss rate is not greater than or equal to, e.g., .2 gallon per hour, otherwise it computes the trend of the data at step 148. If at step 150 it is determined that the trend is greater than .2 gallon per hour, a warning is issued at step 156. In either case, the software continues to read and analyze the data at steps 152, 154, 158 and 160 until the last observation.

The operation of deleting data 170 is shown in detail in Fig. 8. After performing similar analyses at steps 172, 174, 176, 180 and 184, using the indices and the values of the calculated standard deviations as in the routine operation procedure described above, the values of the counters are updated and new data is read at steps 178, 182, 186 and 188. Data is deleted in accordance with steps 178, 186 and 188.

Finally, Fig. 9 shows the delivery calculation in detail. After determining that the cumulative variance is greater than a predetermined value (three standard deviations) at step 192, the program determines whether the variance is greater than, e.g., 100 gallons per minute (step 194). If so, the delivery is recorded and the amount delivered is determined at steps 202 through 220.

If there is a delivery in progress (step 202), data is read until a negative observation to observation variance is observed (step 204). The variance is monitored until the turbulence in the tank subsides (step 206). Thirty
5 observations are read (step 208), and all observations from 15 minutes before the delivery until the end of the turbulence observations are deleted (step 210). An indicator variable is introduced with the turbulence observation, from which regression commences (step 212).
10 The confidence bound on the indicator is computed (step 214). If the confidence bound is within a predetermined tolerance, the volume of the delivery is reported within the confidence bounds (step 220); otherwise, additional
15 observations are added, and the confidence bound is recomputed (step 218).

If the variance between data measurements is less than 100 gallons per minute, the software determines whether the gauges are inoperative and reports them as being inoperative (step 198), or proceeds as in the routine
20 operation procedure according to step 200 (in which there is a negative variance) depending on whether the observed variance exceeds a predetermined value (within one standard deviation) at step 196.

In general, if observed variances are within three
25 standard deviations or other predetermined tolerance of the expected value, the data is stored for future analysis. When cumulative variance exceeds three standard deviations or other predetermined tolerance, different software
30 programs are executed depending on the nature and magnitude of the departure.

If within ten (or other predetermined) successive observations after the initial departure, the cumulative variance returns to within the tolerance range, all data

from and including the initial departure and prior to the initial observation are deleted. The time extent and number of observations involved is recorded and stored for, e.g., a daily gauge performance report.

5 If all ten (or other predetermined) successive observations remain outside the tolerance bound and the cumulative variances are of the same sign, a new trend line is initiated at the point of initial departure. After ten
10 (or other predetermined) additional observations, a third trend line is initiated. If the increment to the overall trend estimated from the most recent observations is not significant, the most recent data is consolidated with the previous data and the process is repeated until such time, if ever, that the current trend increment is significant.

15 If the departure is positive, the system checks whether the product is being dispensed and whether the gauge height fails to decrease, reflecting removal from tank. If so, the tank gauge is reported to be inoperative.

20 If the gauge height is increasing, monitoring is continued as above until the most recent trend line returns to its original slope. Minute to minute variances are monitored to detect turbulence until the gauge values again return to within tolerance. All observations which occurred in the fifteen minutes prior to the first positive departure
25 until the end of post delivery turbulence are deleted. An indicator variable is introduced at the first observation after post delivery turbulence. The system collects thirty additional observations and performs the regression from the beginning of the period to determine the volume delivered.
30 The volume delivered is then reported.

 If the departure is negative, the system proceeds as with delivery. If successive slope increments fail to show a return to the original slope, indicating continuing loss

of product for a predetermined period, typically one hour, and the slope exceeds .2 gallon per hour, the system reports a warning that there is a continuous loss of product. If the loss rate is less than .2 gallon per hour but greater than the minimum detectable leak, the system continues to monitor and recalculate the parameters, to be included in a daily operational report. If the incremental trend line shows a return to the original trend, the system proceeds as with delivery, introduces an indicator variable, deletes data as necessary, and performs the regression to determine the volume of product removed. The system reports a one-time removal of product.

Referring to Fig. 10, the invention incorporates a data acquisition and transmission network (DAT network) 300 to completely automate the process of obtaining, capturing, transferring and processing product inventory data for use in product management, delivery scheduling and environmental compliance practices. DAT network 300 includes on-site processors 302, 304 at the facilities 306, 308 where the tanks are located, a customer host processor 310 and a central host processor 312. DAT network 300 links multiple remote facilities 306, 308 to central host processor 312, which performs the SIR analysis. The link may be accomplished indirectly through customer host processor 310, which itself is connected to a plurality of remote facilities 306, 308. Each of these processor elements is composed of independently operating software and hardware systems which form the basis of a wide area network linked by modems which transmit information electronically via the telephone network 314 using standard dial-up voice grade telephone lines. Examples of DAT networks are the TeleSIRA and ECCOSIRA systems developed by Warren Rogers Associates, Inc., Middletown, Rhode Island.

DAT network 300 provides a uniform method of integrated management for the widest possible variation of underground and above-ground fuel storage, movement and measurement systems. On-site processors 302, 304 are
5 capable of obtaining information from any electronic or mechanical control system, enabling DAT network 300 to accommodate facility configurations that are unique to each facility while presenting the information captured at remote facilities 306, 308 to customer host processor 310 or
10 central host processor 312 in a uniform format.

On-line processors 302, 304 obtain and capture product inventory data through the use of proprietary interfaces with external systems in use at remote facility 306, 308, such as tank gauges and sales recording devices.
15 On-line processors 302, 304 transfer captured information daily, weekly or monthly through the public switched telephone network 314 to customer host processor 310 or central host processor 312 for use in inventory management, delivery scheduling and/or environmental compliance. On-
20 site processors 302, 304 may be, e.g., touch-tone telephones acting as sending units and Windows-based multi-line, voice prompt/response PC's as the receiving units. On-site processors 302, 304 may be designed to meet the specific needs of facilities 306, 308 without requiring remote
25 hardware at the facility in addition to that already present.

In particular, each of on-site processors 302, 304 typically is equipped with an alphanumeric keypad, a character display, a power supply, four programmable serial
30 communication ports, an internal auto-dial/auto-answer (AD/AA) modem and a local printer port (for connection to a printer). The keypad and display allow for operator configuration and manual entry of sales, delivery and tank

level data. Use of an AD/AA 2400 baud modem allows multiple on-site processor 302, 304 to share an existing voice grade telephone line by establishing communication windows to minimize attempted simultaneous use. Each of the programmable serial communication ports is independent, fully programmable and governed by options selected at the facility or off-site through modem access. Finally, on-site processors 302, 304 can prompt the facility operator to enter missing or suspect entries when results are outside the expected range.

The use of customer host processor 310, which is capable of receiving, storing and processing information from multiple on-site processors 302, 304, enables the management of a remote tank population from a single point of contact. A database of information created by customer host processor 310 is the basis for all higher level product management functions performed by DAT network 300. The database is also the basis for the environmental compliance analysis performed by central host processor 312.

The use of central host processor 312, which is capable of receiving, storing and processing the information in the database created by customer host processor 310 for product management enables DAT network 300 to achieve maximum results by utilizing the database for environmental compliance without additional remote facility information or communication. Central host processor 312 is capable of transmitting a resulting database of the environmental analysis back to customer host processor 310 for printing and other customer record-keeping requirements.

The processor elements of DAT network 300 may exhibit other useful operational characteristics. To prevent unauthorized access to DAT network 300, a security access code for dial-up data transfer functions is required.

Under secured access, the baud rate, parity, stop bit parameters and communication protocol are determined at any of on-site processors 302, 304, customer host processor 310 or central host processor 312.

5 Another function of DAT network 300 is to monitor tank contents generally. DAT network 300 can be programmed to activate, e.g., an audible and visual alarm if the water level in the tank is too high (e.g., greater than 2 inches),
10 if the product level in the tank is too high (e.g., more than 90% of tank capacity) or too low (e.g., less than 10% of tank capacity, more product must be reordered, or less than two days supply), and if a theft occurs (product level changes during quiet periods).

15 The system may be used to obtain valuable information other than inventory regulation and leak detection. For example, the system may incorporate time series analysis routines, including Box Jenkins, moving average and exponential smoothing, to derive estimates of demand for the product which also incorporate temporal and
20 seasonal trends and special events.

 The demand analysis may also be combined with additional inputs of holding costs, reorder costs, transportation costs and penalty costs for running out of stock. The system can include optimal inventory algorithms
25 to determine optimal order quantities, reorder points and optimal delivery truck routing. Further, the system may incorporate multiechelon, optimal inventory procedures to accommodate combined wholesale and retail operations, such as with calculus-based optimization and linear, nonlinear
30 and dynamic programming.

 As shown in Fig. 13, a DAT network may include a fuel access control unit or system 510 at a storage tank facility 500 such as a UST automobile fueling facility.

Fuel access control unit 510 is a dispensing system actuated by the use of a device coded with information, e.g., a card 520 with a coded magnetic stripe 522, e.g., an optical punched card, an electrically erasable programmable read-only memory (EEPROM) key, a radio frequency identification (RFID) tag, a magnetic resonance coupler, a bar code, or other type of coded medium which contains identification information pertaining to the user. Fuel access control unit 510 may include apparatus for a user to input information, e.g., a card reader 512, a display 514, and a keypad 516, a control system 562 for turning a fueling dispenser 560 on and off, and a processor 564 or similar computing platform for controlling and monitoring the user's fueling process. Manufacturers of fuel access control system which rely upon optical reading devices or magnetic stripe card reading devices to identify the user include FillRite, Fuel Master, Gasboy, PetroVend and Trak Engineering.

Fuel access control unit 510 is used to monitor the activity of fueling dispenser 560. Fueling dispenser 560 includes a hose 566 for dispensing fuel from a tank 515, a totalizer 568 and a meter 569 for measuring the volume of fuel dispensed by hose 566. Fuel access control unit 510 may communicate with an on-site processor 530 located inside facility building 540 over a local area network (LAN). The communications between fuel access control unit 510 and on-site processor 530 may be over RS-232/RS-485/RS-485 (MultiDrop) cabling 542.

Fuel access control unit 510 provides a system of controlling access to fueling facility 500 by determining the identity of each user of the facility and screening each user based on his or her authority to purchase fuel. Identification of the user is made by requiring the user to

~~WO 01/04586~~~~PCT/US00/18743~~

present a valid magnetic card (e.g., card 520), an optical punched card, an EEPROM key, an RFID tag, a magnetic resonance coupler, a bar code, or other type of coded medium, which contains identification information pertaining to the user. Such fuel access control systems are referred to as island control units or cardlock system. Further, the user may be required to present additional identifying data by other means such as buttons, key switches, or by entering information on keypad 516. Once the identification data is collected, fuel access control unit 510 determines the user's fueling privileges, and based on this information will either allow or deny fueling by the user. If fueling is allowed, fuel access control unit 510 will enable dispensing pump 560 for that particular user and monitor the fueling process. At the completion of the fueling process, fuel access control unit 510 will record the amount of the fueling transaction in a memory 567 and retain the recorded information for further accounting of the transaction.

Fuel access control unit 510 may be used to perform a variety of functions, including the following:

1. Identifying the user by reading a card or other coded medium and collecting the user's identification information such as a driver license number or other personal data.
2. Collecting other pertinent data for analysis, such as an identification of the user's vehicle, the vehicle's odometer reading, a trip number, the trailer hub counter, the engine hour reading and/or a refrigerator unit hour reading.
3. Making authorization decisions, to determine whether the identified user is permitted to obtain fuel.
4. Enabling fueling by enabling the proper dispensing pump for the user.

5. Monitoring fueling by controlling the maximum amount dispensed.
 6. Turning off the dispensing system if no fuel is dispensed for a predetermined period of time.
 - 5 7. Recording the fueling transaction by storing the final amount of fuel dispensed.
 8. Reporting the fueling transaction to a processing location for inventory analysis or other analysis.
- There are two types of authorization procedures for

10 determining whether an identified user is permitted to obtain fuel from a fueling facility. Fuel access control unit 510 may use either or both of these authorization procedures. For the first method of authorization, external authorization, fuel access control unit 510 collects the

15 user's information and forwards the collected information to an outside agent to make a final decision as to whether or not the identified user is permitted to obtain fuel from fueling facility 500. The outside agent may return an

20 approval, along with fueling parameters (i.e., a maximum amount), or a denial. Fuel access control unit 510 will then inform the user whether or not fuel may be obtained. The outside agent may be connected to fuel access control unit 510 via a dial-up telephone line, a LAN or a direct communication link.

25 For the second method of authorization, internal authorization, fuel access control unit 510 collects the user's information and compares the collected information to a data table stored locally to make the final decision as to whether or not to allow fueling. The locally stored table

30 may return an approval, along with fueling parameters (i.e., a maximum amount), or a denial. Fuel access control unit 510 will then inform the user whether or not fuel may be obtained. The locally stored table may be housed directly

in fuel access control unit 510, in a control device at the fueling facility such as on-site processor 530 or carried on the access medium (e.g., card 520) used to request fueling authorization. The locally stored table may also be imbedded directly in fuel access control unit 510 or
5 accessed via a LAN inside the fueling facility's building 540.

Fuel access control unit 510 functions as an additional point of sale (POS) device, similar to sales recording device 71 (Fig. 1). Fuel access control unit 510
10 responds to requests for hose status and totalizer and meter values in the same manner as a POS device. Fuel access control unit 510 also monitors each hose 566 and tracks status changes in the hose, including indications that the
15 hose is idle, that a request for access is in process, that the use of hose 566 has been authorized, that the hose has been taken off its hook, that dispensing pump 560 is dispensing fuel with hose 566 removed from its hook, and that the dispensing pump has been turned off and the hose is
20 idle again.

Each detailed transaction that is completed by fuel access control unit 510 may be retrieved by on-site processor 530 from memory 567 upon completion of the transaction. The transaction information may be stored in
25 processor 530 for further analysis. Further, based on the stored, detailed transaction information, a detailed site dispensing audit can be performed. Such a site dispensing audit would determine whether the volume claimed to be dispensed by fuel access control unit 510 actually
30 represents the volume change in the UST or AST during the same period as calculated by on-site processor 530.

In conventional cardlock applications as well as other transaction authorization procedures, the processing

WO 01/04586

methods assume that the volume as determined by fuel access control unit 510 is accurate, but have no way of determining if any errors in calculating the volume have occurred. A fuel access control system interfaced directly with an on-site processor 530 that receives data from an automatic tank gauge 580 may also experience similar errors associated with conventional inventory control practices. By contrast, an enhanced, integrated fuel access control unit 510 may include an accurate analysis of the state of hose 566. Such an integrated fuel access control unit 510 may avoid the occurrence of dispensing pump 560 being properly accessed and enabled by authorization control system 562, but appearing not to be dispensing fuel. From the point of view of fuel access control unit 510, the user may have simply changed his mind about purchasing fuel. However, from the perspective of on-site processor 530, a determination can be made about the dispensing pump's activity by analyzing the tank activity and comparing that information to the activity of totalizer 568 and meter 569. Further, although other hoses may be actively dispensing fuel during the same period, on-site processor 530 may track all hose activity independently for analysis.

Other embodiments are within the scope of the claims.

What is claimed is:

~~Druckexemplar~~

CLAIMS

1. A method of monitoring a fluid storage and dispensing system including a dispensing apparatus,
5 the method comprising:
dispensing a quantity of fluid from the system using the dispensing apparatus based on an authorisation;
collecting a plurality of measurement data from
10 the dispensing apparatus in a format readable by the computer;
collecting a plurality of dispensing apparatus activity data including a state of the dispensing apparatus in a format readable by a computer;
15 storing the plurality of measurement data and the plurality of dispensing apparatus activity data in a memory;
determining the mathematical relationship between a volume of fluid in the storage tank and
20 height of fluid in the storage tank; and
statistically analysing the stored plurality of measurement data and the mathematical relationship to calculate a volume of fluid based on the plurality of measurement data collected from the
25 dispensing apparatus.
2. The method of claim 1 wherein the authorisation is based on information relating to a user requesting that the quantity of fluid be dispensed from the
30 system.
3. The method of claim 1 wherein the authorisation as provided by a fuel access control system.
- 35 4. The method of claim 1 further comprising

transmitting the plurality of measurement data to a processor to perform the statistically analysing step.

5 5. The method of claim 1 wherein the dispensing apparatus includes a totaliser and a metre.

6. The method of claim 1 wherein the plurality of measurement data is stored in compressed matrix form.

7. The method of claim 6 wherein the compressed matrix is a product of the data matrix and a transpose of the data matrix.

15 8. A method of monitoring a fluid storage and dispensing system including a plurality of dispensing apparatuses, the method comprising:
dispensing a quantity of fluid from the system
20 using the plurality of dispensing apparatuses based on an authorisation;

simultaneously collecting measurement data and dispensing apparatus activity data from the plurality of dispensing apparatuses in a form a readable by a computer, wherein the dispensing apparatus activity data includes the state of the dispensing apparatus;

repeating the collecting step to obtain a plurality of the measurement data;

30 storing the plurality of the measurement data in a memory; and

statistically analysing the stored plurality of measurement data to calculate a volume of fluid based on the plurality of measurement data collected from the dispensing apparatus.

35

- 5
9. A method of claim 8 wherein the authorisation is based on information relating to a user requesting that the quantity of fluid be dispensed from the system.
10. A method of claim 8 wherein the authorisation is provided by a fuel access control system.
- 10 11. The method of claim 8 further comprising transmitting the plurality of measurement data to a processor to perform the statistically analysing step.
- 15 12. The method of claim 8 wherein the plurality of measurement data is stored in compressed matrix format.
- 20 13. The method of claim 12 wherein the compressed matrix is a product of a data matrix and a transpose of the data matrix.
- 25 14. A fluid storage and dispensing system, comprising:
a tank for storing fluid;
a dispenser for dispensing fluid from the tank;
a fuel access control system for enabling the dispenser based on an authorisation;
measurement apparatus for collecting measurement data corresponding to a quantity of fluid dispensed from the tank by the dispenser and for collecting dispensing apparatus activity data including a state of the dispensing apparatus; and
30 a processor for statistically analysing a measurement data to calculate a volume of fluid in the system based on a mathematical relationship
35 between a volume of fluid in the storage tank and a

height of the fluid in the storage tank.

15. A system of claim 14 further comprising a memory for storing the collected measurements data.
- 5
16. The method of claim 14 wherein the fuel access system is activated by a coded medium which contains identification information pertaining to the user and which constitutes a request to dispense fluid from the system.
- 10
17. A system of claim 14 wherein the authorisation is based on information about a user requesting to dispense fluid from the system.
- 15
18. The method of claim 14 wherein the measurement apparatus comprises a totaliser and a metre.
19. The system of claim 14 wherein the processor stores a measurement data in a compressed matrix format.
- 20
20. The system of claim 19 wherein the compressed data matrix is a product of a data matrix and a transposer for data matrix.
- 25
21. The method of claim 1 wherein the fluid storage and dispensing system is a manifolded system.
22. The system of claim 14 wherein the fluid storage and dispensing system is a manifolded system.
- 30
